POPULATION PROJECTIONS

1987 Version

Dover, Delaware

January, 1988

Summary of Projection Methodology

Introduction.

In 1975, a group of state and local agencies joined together in an attempt to bring some degree of sanity to the projection process. At that time, many of these agencies (or their consultants) produced separate projection series.

The problem faced by planners and policy makers alike was in choosing among the projection series available. This led to inconsistencies in the execution of policy where one set was used for traffic planning, another for water demand analysis, and a third for school enrollment or health planning. This is the same problem that was faced by DEFAC (Delaware Economic and Financial Advisory Council) in preparing revenue forecasts for the Governor and the General Assembly. Members of the General Assembly forced the abandonment of the range concept in favor of a "best guess" or "most likely" outcome. The general opinion was that ranges permit the manipulation of the data to fit the user's purposes. That was the guiding force behind the "joint" production of population estimates.

After producing projection series in 1975, 1978 and 1982, the Consortium decided to try to bring coherence to the employment projection series and more importantly, to make sure that the population forecasts and employment forecasts were consistent. The general logic was that you cannot have population growth without employment opportunity in the long-run. That decision led to the basic framework of the projection model that is currently used and is a departure from the more common approach which had been used prior to 1984.

In the final analysis, the quality of the projections depends on the quality of the assumptions chosen by those making the projections. In this paper we will explain the

assumptions used and the projection process to which they are the primary input.

The Model.

The projection process begins with the 1980 age-sex distribution (obtained from the Census) for the jurisdiction being projected. In earlier years this distribution began with the five-year cohort 0-4 and ended with the 75&over age group. This year, the detail has been expanded so that the last group is now 85&over.

The first step in the process is to age each age-sex cohort by five years. In doing so, a certain number of deaths must be accounted for. A five year survival rate is used to account for these deaths. Applying the survival rate to the 0-4 age group gives the number of those persons alive in that age group in 1980 that will constitute the 5-9 age group in 1985. This procedure is followed until all age groups have been filled with the exception of the birth cohort (0-4 in 1985).

The 0-4 age group in 1985 will be formed from all of those persons born during the 1980-1985 period. We estimate this by applying an annual birth rate for females in each separate age group beginning with 10-14 and ending with 45-49. The projected of births are then survived to 1985.

This procedure can then be applied for each subsequent time period 1985-1990, 1990-1995, and so on. The result would be an estimate with the assumption of zero net-migration. Unfortunately, that is rarely the case and thus we must attempt to account for migration.

The typical procedure used to adjust the projection for net-migration is to calculate a migration rate for each age-sex category for some past time period e.g. 1970-1980 or 1975-1980, and to make assumptions about how those rates will change in the future. In order to integrate the

employment projections with the population projections we have chosen a variant of the usual procedure.

If we forecast employment using some economic model, then the population must be sufficient to provide the laborforce to fill that employment. If the current population is too low, net in-migration is forecasted. If the forecasted population is too high, out-migration will occur. In either case, the migration rates from the past are modified proportionally to permit the employment forecasts and the population forecasts to balance. These modified migration rates are then applied to the survived population for each five-year period. The actual amount of migration is an output of the calculation. If this number seems too high then adjustments must be made to the employment forecasts or to one of the other assumptions in the laborforce estimate.

This is the basic core of the model that was used to produce the attached projections.

Mortality.

The survival rates currently used in the model are attached. They are based on age by sex, five year survival rates provided by the Bureau of Census in their projection series (1983 to 2080). These rates are the middle mortality assumptions. Using these as a base, they were scaled proportionally to produce the number of deaths actually observed in the State in the period 1980-1985. Thus, although they are national figures they do relect accurately Delaware conditions. The same set of assumptions were applied to all jurisdictions in the State.

Fertility.

The asuumptions for birth rates were derived from data supplied by the Bureau of Census in their projection series. These estimates were also scaled proportionally to produce the observed number of births during the 1980-1985 calibration period. The table is attached.

Institutional Populations.

In order to avoid forecasting births from females in the University population we have chosen to exclude part of the University from all of these projections. For affected jurisdictions, they are simply removed at the beginning and added in at the end. The differential treatment of the University dormitory population was made necessary since very different birth rates and labor force participation rates apply to this population. For those living off-campus the data were simply not available. The University's student body is over 17,000 of which approximately 8,800 live on campus. It would be expected that the others would be somewhat different than the general population.

This has in fact led to difficulties in forecasting school enrollment in the Greater Newark area. For the State and New Castle County, we must assume that any bias caused by excluding students who will ultimately live and work in Delaware is offset with the inclusion of out-of-state students who live off campus. It is a difficult population.

Laborforce.

In order to balance the employment forecast with the population projection we have to calculate resident employment. That requires a number of assumptions. The first set of assumptions are taken from the Bureau of Labor Statistics. Those give us laborforce participation rates for each age-sex cohort from 1985 through 2010. They are projections themselves. Applying these assumptions allows us to derive a theoretical laborforce. To that laborforce is applied the same assumption on unemployment that was used in generating the employment forecasts. The result is employment by place of residence. From that projection an estimate of jobs is derived, to which adjustments are made for self-employment, agricultural jobs, and multiple job holders. The result is resident jobs, totally derived from the population projection.

We use the Delmarva Power and Light Company's employment forecast as a starting point from the employment side. A single adjustment is required to reach an estimate for resident jobs and that is in-commuting.

In-commuting is a difficult parameter and it is the weakest part of the entire projection process. Our primary source is the UTPP file provided by the Bureau of Census. It measures commuting at one point in time namely the 1980 Census. Further, commuting in Kent and Sussex counties is not separable. We also have conflicting data from the Bureau of Economic Analysis and the Division of Revenue which further complicates the matter. Fortunately, the size of this part of the laborforce is relatively small and should not by itself impact the overall process.

Adjustments.

This set of projections is a starting point and must be carefully reviewed annually. There are a number of sources which can be used to adjust the path of the projection without going through a major revision. First, the annual population estimates (not forecasts) provided by the Federal-State-Local cooperative are useful for overall monitoring. Second, actual birth and death statistics issued by NCHS and the State Bureau of Vital Statistics are quite valuable. Third, school enrollment data, medicare enrollment data and the current population survey can help with structural changes in the age-groups. Finally, data from the State Department of Labor can help spot changes in the path of employment. It is imperative that these indicators be tracked and that the projections be modified annually.

DELAWARE POPULATION CONSORTIUM

POPULATION PROJECTIONS

1988 Version

Dover, Delaware
January, 1989

Summary of Projection Methodology

Introduction.

In 1975, a group of state and local agencies joined together in an attempt to bring some degree of sanity to the projection process. At that time, many of these agencies (or their consultants) produced separate projection series.

The problem faced by planners and policy makers alike was in choosing among the projection series available. This led to inconsistencies in the execution of policy where one set was used for traffic planning, another for water demand analysis, and a third for school enrollment or health planning. This is the same problem that was faced by DEFAC (Delaware Economic and Financial Advisory Council) in preparing revenue forecasts for the Governor and the General Assembly. Members of the General Assembly forced the abandonment of the range concept in favor of a "best guess" or "most likely" outcome. The general opinion was that ranges permit the manipulation of the data to fit the user's purposes. That was the guiding force behind the "joint" production of population estimates.

After producing projection series in 1975, 1978 and 1982, the Consortium decided to try to bring coherence to the employment projection series and more importantly, to make sure that the population forecasts and employment forecasts were consistent. The general logic was that you cannot have population growth without employment opportunity in the long-run. That decision led to the basic framework of the projection model that is currently used and is a departure from the more common approach which had been used prior to 1984.

In the final analysis, the quality of the projections depends on the quality of the assumptions chosen by those making the projections. In this paper we will explain the assumptions used and the projection process to which they are the primary input.

The Model.

The projection process begins with the 1980 age-sex distribution (obtained from the Census) for the jurisdiction being projected. This distribution begins with the five-year cohort 0-4 and ends with the 85&over age group.

The first step in the process is to age each age-sex cohort by five years. In doing so, a certain number of deaths must be accounted for. A five year survival rate is used to account for these deaths. Applying the survival rate to the 0-4 age group gives the number of those persons alive in that age group in 1980 that will constitute the 5-9 age group in 1985. This procedure is followed until all age groups have been filled with the exception of the birth cohort (0-4 in 1985).

The 0-4 age group in 1985 will be formed from all of those persons born during the 1980-1985 period. We estimate this by applying an annual birth rate for females in each separate age group beginning with 10-14 and ending with 45-49. The projected of births are then survived to 1985.

This procedure can then be applied for each subsequent time period 1985-1990, 1990-1995, and so on. The result would be an estimate with the assumption of zero net-migration. Unfortunately, that is rarely the case and thus we must attempt to account for migration.

The typical procedure used to adjust the projection for net-migration is to calculate a migration rate for each age-sex category for some past time period e.g. 1970-1980 or 1975-1980, and to make assumptions about how those rates will change in the future. In order to integrate the employment projections with the population projections we have chosen a variant of the usual procedure.

If we forecast employment using some economic model, then the population must be sufficient to provide the laborforce to fill that employment. If the current population is too low, net in-migration is forecasted. If the forecasted population is too high, out-migration will occur. In either case, the migration rates from the past are modified proportionally to permit the employment forecasts and the population forecasts to balance. These modified migration rates are then applied to the survived population for each five-year period. The actual amount of migration is an output of the calculation. If this number seems too high then adjustments must be made to the employment forecasts or to one of the other assumptions in the laborforce estimate.

This is the basic core of the model that was used to produce the attached projections.

Mortality.

The survival rates currently used are based on age by sex, five year survival rates provided by the Bureau of Census in their projection series (1983 to 2080). These rates are the middle mortality assumptions. Using these as a base, they were scaled proportionally to produce the number of deaths actually observed in the State in the period 1980-1985. Thus, although they are national figures they do accurately reflect Delaware conditions. The same set of assumptions were applied to all jurisdictions in the State.

Fertility.

The assumptions for fertility rates were derived from data supplied by the Bureau of Census in their projection series. These estimates were also scaled proportionally to produce the observed number of births during the 1980-1985 calibration period.

Institutional Populations.

In order to avoid forecasting births from females in the University population we have chosen to exclude part of the University from all of these projections. For affected jurisdictions, they are simply removed at the beginning and added in at the end. The differential treatment of the University dormitory population was made necessary since very different birth rates and labor force participation rates apply to this population. For those living off-campus the data were simply not available. The University's student body is over 17,000 of which approximately 8,800 live on campus. It would be expected that the others would be somewhat different than the general population.

This has in fact led to difficulties in forecasting school enrollment in the Greater Newark area. For the State and New Castle County, we must assume that any bias caused by excluding students who will ultimately live and work in Delaware is offset with the inclusion of out-of-state students who live off campus. It is a difficult population.

Laborforce.

In order to balance the employment forecast with the population projection we have to calculate resident employment. That requires a number of assumptions. The

first set of assumptions are taken from the Bureau of Labor Statistics. Those give us laborforce participation rates for each age-sex cohort from 1985 through 2010. They are projections themselves. Applying these assumptions allows us to derive a theoretical laborforce. To that laborforce is applied the same assumption on unemployment that was used in generating the employment forecasts. The result is employment by place of residence. From that projection an estimate of jobs is derived, to which adjustments are made for self-employment, agricultural jobs, and multiple job holders. The result is resident jobs, totally derived from the population projection.

We use the Delmarva Power and Light Company's employment forecast as a starting point from the employment side. A single adjustment is required to reach an estimate for resident jobs and that is in-commuting.

In-commuting is a difficult parameter and it is the weakest part of the entire projection process. Our primary source is the UTPP file provided by the Bureau of Census. It measures commuting at one point in time namely the 1980 Census. Further, commuting in Kent and Sussex counties is not separable. We also have conflicting data from the Bureau of Economic Analysis and the Division of Revenue which further complicates the matter. Fortunately, the size of this part of the laborforce is relatively small and should not by itself impact the overall process.

Adjustments.

This set of projections is a starting point and must be carefully reviewed annually. There are a number of sources which can be used to adjust the path of the projection without going through a major revision. First, the annual population estimates (not forecasts) provided by the Federal-State-Local cooperative are useful for overall monitoring. Second, actual birth and death statistics issued by NCHS and the State Bureau of Vital Statistics are quite valuable. Third, school enrollment data, actual births, deaths, and estimated migration forthemedicare enrollment data and the current population survey can help with structural changes in the age-groups. Finally, data from the State Department of Labor can help spot changes in the path of employment. It is imperative that these indicators be tracked and that the projections be modified annually. All projections were carefully benchmarked to known data in 1985 (e.g. actual births, deaths, and estimayed migration for the 1980-1985 period).

Interpolation.

The tables containing age distributions now include entries for the years 1981-1984 and 1986-1989. These estimates are derived by calculating the compound annual growth rate between 1980-1985 and 1985-1990 respectively. This calculation is done separately for each age group and the totals reflect the sum of the results not the interpolated total.

Notice

All of projections have been rounded to the nearest 50. This is no way should be interpreted as a measure of statistical accuracy. Further, this rounding may produce differences between the sum of a table and the printed totals. The total is the rounded sum of the column; not the sum of the rounded entries of the column.

RACIAL PROJECTIONS

This is the first year that race has been included in the Consortium's projections. As a result, the Consortium has endorsed these racial projections as experimental. The Consortium encourages users to review these figures in detail and to forward written comments to our office in Dover concerning their accuracy.

Users are also invited to attend our yearly Methodology Subcommittee meetings which take place during the summer. We will review the methodology used to produce these figures at that time. If these figures meet with users expectations, the Consortium will consider officially endorsing race as a legitimate component of the projections at our annual meeting in January 1990.
